1 Introduction

Given the scale of the web and how far information can be spread, it can be difficult for avid gamers to follow news for their favorite games. Thousands of games are released annually (Gough, 2019a; Gough, 2019b), with some of those games spending up to nine years in development (Dietz, 2011). Information regarding game development is often decentralized and widespread across many different news sites, developer blogs, streaming platforms, and social media. This spread of information can make it both difficult and time-consuming for gamers to find new information for games in development.

Figure 1

Current Process Flow

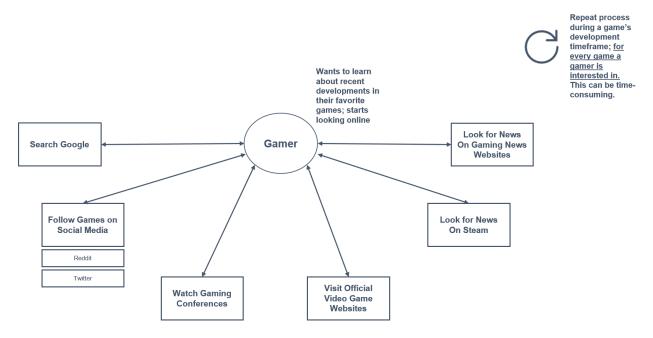

Figure 1 shows the current process flow of a gamer looking for information about an upcoming game. To stay up-to-date with the game's development prior to release, the gamer will have to actively and regularly check each source for any new information released; this is an active process that involves dealing with a lot of "noise" both before and after a game is released, and can be applicable to multiple games at once. This kind of routine can be both time-

consuming and exhausting, which can lead to gamers doing less news-searching and risk missing out on new information. As a result, gamers can often miss out on games they would have enjoyed playing. This poses a huge challenge for small, independent (indie) developers to keep attention on their games, both released and upcoming, as they become overshadowed by larger, more popular triple-A (AAA) franchises.

In order to alleviate having to keep track of a large amount of information and sources at once, gamers need a single repository to find all the news for their favorite games. They need a platform that is accessible, customizable, and capable of notifying them when new news is released while also filtering out any unwanted information. This will keep gamers up-to-date with the games they follow and help prevent any loss in retention for smaller games that struggle with maintaining and growing player populations.

The solution is GameEye, an application that allows gamers to keep up-to-date with their favorite games. GameEye collects news for games online and links the user directly to the sources. GameEye is intended for those who play video games either as a serious or casual hobby. These gamers will want to stay informed about their favorite games throughout their development cycles; they will be updated and notified about new information as it is released. Small indie developers can be considered indirect customers as they benefit from their games gaining more exposure and retaining players over a longer period of time as they release new games or updates to existing titles.

2 GameEye Product Description

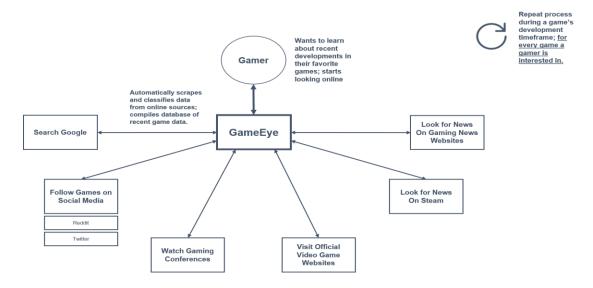

GameEye is a progressive web application (PWA) for computers and mobile devices that allows users to craft a personal watch-list of their favorite games and receive notifications when any news or updates for those games is released. GameEye is able to scour the internet to find

news about specified games and consolidate it in one location for convenient viewing. This is handled through the use of web scrapers to collect links to game-related news from various sources of game-centric news aggregators. Machine learning is utilized to classify these news sources using a multi-factor scoring system to determine the importance of news updates for use in filtering unimportant content and notification customization. Users are able to easily search for and add games, both current and unreleased, to their personal, customizable watch-list.

2.2 Key Product Features and Capabilities

GameEye features many robust features to help gamers improve their quality of life when looking for game news. Figure 2 represents the updated process flow with the use of GameEye; instead of the gamer having to constantly navigate between news sources to find information, GameEye handles the same workload so the gamer can view the information in one location. This streamlines both the time and effort needed to stay up-to-date with a game's development.

Figure 2
Solution Process Flow

The user is able to build their own watch-list of games; these can be games that are either already released or still in development. Each game in a user's watch-list contains categorized

information as represented in Figure 3. When a new piece of information is found, it is given a label depending on source information and a notification is sent to the user.

Figure 3

Information Categories Mock-Up

The categories of posts represented in Figure 3 include important updates such as changes in release dates or new game updates, news articles pertaining to the game, social media posts from development teams, official or community artwork, and videos on streaming sites such as trailers or developer documentaries. When new content is discovered, notifications are sent to the user through push-notifications or email if the user specifies. On the application itself,

the number of new notifications since the user previously logged in are shown next to each category.

Figure 4

News Articles Mock-Up

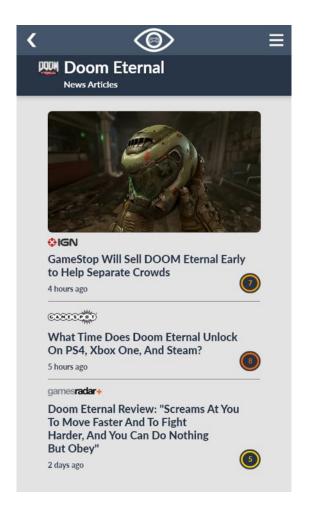

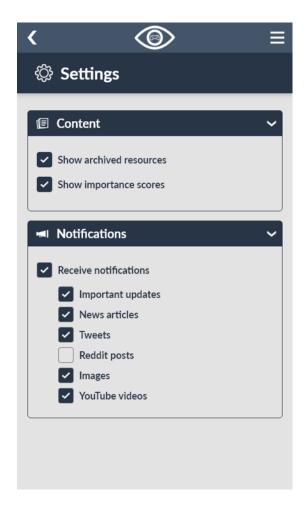

Figure 4 shows how the articles are represented when visiting the "news articles" category. If available, an image from the most recent article is provided for viewing above the articles listed, and each article is accompanied by the name of the news outlet. Each article is given a score based on its importance generated by machine learning algorithms, and directs the user to the original news source. Any content in these categories that are over ninety days old will be removed from the listing and archived for later viewing at the user's discretion.

Figure 5
Settings Mock-Up

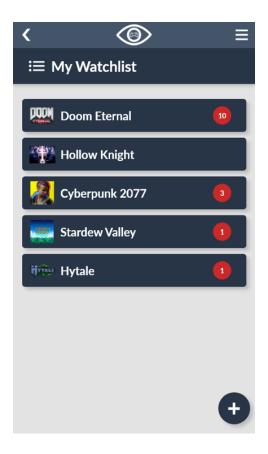

Shown in Figure 5, the user is able to modify notification settings to change what kind of notifications they get and the frequency in which they are notified. Users have the option to customize the notifications they receive from the different categories; and, if desired, users have the capability to enable or disable the scoring for incoming news and the ability to view archived information. Users are also given the option to customize which games from their watch-list in which they wish to receive notifications.

GameEye requires registering an account with an email and password in order to access its features. GameEye users take on one of two main roles: guest and registered user. A guest is

anyone that visits the application who is not registered; a guest is only able to register for an account and learn more about the GameEye application. Registered users are those who have registered an account and can begin curating their watch-list and receiving notifications.

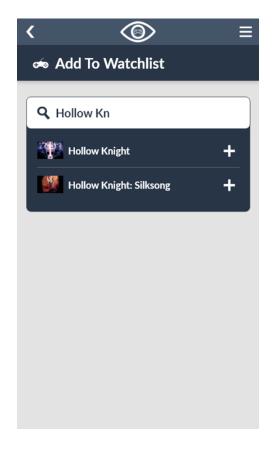

Figure 6

User Watch List Mock-Up

Games are tracked through the user's watch-list as represented in Figure 6. Through the watch-list, a user can see all the games they follow and if any new content is available for viewing; interacting with a title in the watch-list takes the user to the categorized information related to that game. The watch-list can also be customized to fit the user preferences such as sorting order and which games can send alerts.

Figure 7
Searching Mock-Up

When searching for games to add to the watch-list, GameEye utilizes a search bar with auto-completion, as demonstrated in Figure 7, to find games and directly add them to the watch-list. When searching for a game, game titles and their respective information is retrieved from an existing video game database, such as the IGDB database or potentially a curated database of games. GameEye also provides a list of current popular games based on user activity to serve as suggestions for users.

[This space intentionally left blank]

Figure 8

Web Scraping Flow Diagram

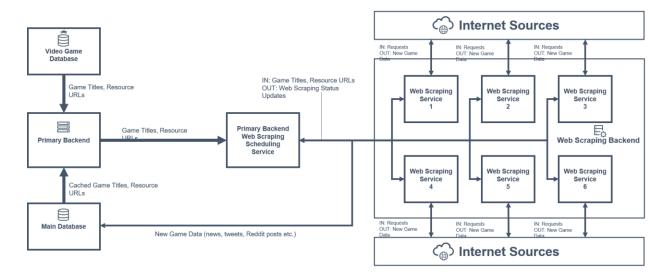

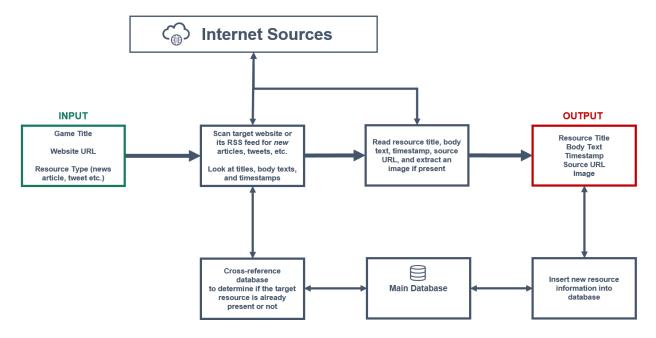

Figure 8 shows the flow diagram for how the web scraping works on GameEye's backend. Web scraping services are developed to monitor different sources of information across the internet such as news aggregators, social media, online store pages like Steam, and streaming services. When new information is found, the scraper is able to provide collectively the title of resource found, the text tied to the resource, the resource URL, a timestamp of when the resource was found, and any potential thumbnail back to the GameEye database to be used for processing; this process is represented in Figure 9. The resource type for the article is determined and stored in the appropriate category under the related game.

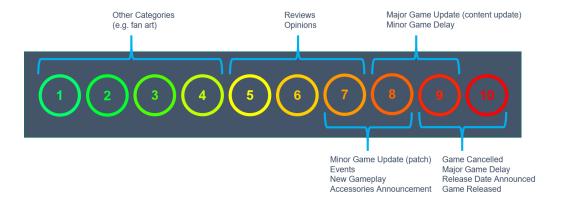

Figure 9

Web Scraping Service Algorithm

With the information provided by the web scrapers, GameEye will utilize machine learning algorithms to observe the resources and determine "impact" scores for each resource to help users determine how significant the information is. These scores range from one to ten with one being of low impact that may be of little interest to the user, and ten being high impact which the user would need to know in regards to development. This scale is shown in Figure 10.

Figure 10
Impact Score Scale

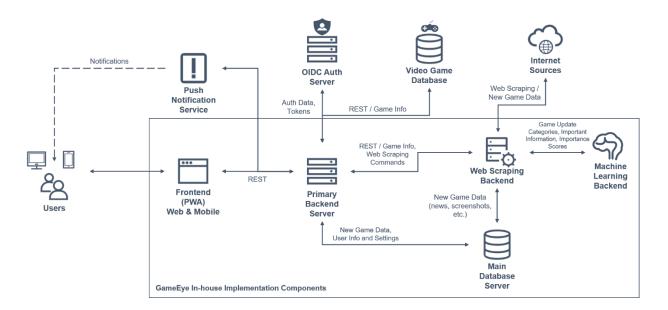

These scores help to both prioritize user attention to important news for their tracked games and allow for further customization of the news they wish to be notified about. If a user was only concerned with major game updates or announcements in regards to game releases, they have the capability to limit their notifications to news resources with higher scores; this functionality helps in keeping any unimportant news users may not be concerned with out of their watch lists.

2.2 Major Components (Hardware/Software)

The hardware used by GameEye is the frontend server, main backend server, web scraping server, main database server, and machine learning backend server. Figure 11 shows the Major Functional Component Diagram (MFCD) for GameEye. The main components outside of the frontend, backend, and main servers are the video game database to retrieve video game titles, the web scraping backend, and the associated machine learning backend.

Figure 11

Major Functional Component Diagram

The frontend server is an external-facing web server responsible for handling the frontend of the web application. The main backend is an external-facing web server exposing a REST API for communication between the frontend, web scraping backend, databases, and other third-party services. The web scraping server is also external-facing, but doesn't monitor incoming traffic; this server also exposes a REST API for launching web scraping operations. The machine learning backend is an internal GPU-powered TensorFlow Serving server exposing a REST API for machine learning inference; it communicates directly with the web scraping server to extract information and classify data. The main database server is an internal MongoDB server that contains all data related to the GameEye application.

GameEye utilizes the Angular Framework and Google Workbox through the WebStorm IDE to handle the frontend work. The main programming languages used for the frontend are HTML, SASS/CSS, and TypeScript. The backend of GameEye uses the Spring Framework, jsoup library, and the MongoDB Java Driver through the IntelliJ IDEA IDE. The main programming language used for the backend is Java. Testing for GameEye and all its functions is handled with the JUnit Java Framework and the Jest JavaScript Framework.

MongoDB, MongoDB Compass and the IGDB REST API is used to build and maintain the GameEye databases. For third-party software, GameEye uses the Auth0 Single Page App SDK for account authentication and Firebase Cloud Messaging to handle notifications on mobile devices. The software used to handle the machine learning algorithms are the Keras library, scikit-learn library, and a TensorFlow Serving model server. The primary programming language that GameEye uses for all forms of machine learning is Python. For natural language processing, GameEye will utilize the spaCy library which is used with Python.

3 Identification of Case Study

GameEye is targeting both casual and hardcore groups of gamers who want to keep track of their favorite games and upcoming releases; the future user base isn't expected to deviate from the intended target audience. Upon initial deployment, the case study group will be comprised of members from the ODU Gaming Club who are looking forward to new game releases over the course of 2021 and beyond. The GameEye application will require at least 4 users to properly test functionality. The users in this group will be tracking upcoming games and receiving notifications as news for these games become available. The users will be able to submit feedback within the application on current, live features and features they would like to have add in the future. There will also be an option for these users to request new games to follow if they are not present in the database; this will assist in further expanding GameEye's searching functionality and improving web scraper efficiency.

4 Prototype Description

The GameEye prototype will demonstrate the major functions of the real-world product. These functions include watchlist construction, scraping for game news articles, impact scoring for scraped articles, account creation and management, and database construction. The biggest difference in functionality between the prototype and the real-world prototype is the scope of resources available to users. The prototype will only feature game information from online news articles, while the real-world product will also provide Twitter posts, YouTube videos, and Reddit posts. These differences are shown in Figure 12.

4.1 Architecture

The prototype will be utilizing the same architecture as the real-world product; however, the prototype will not be utilizing the replicated servers that would be present in the real-world

LAB 1 – GAMEEYE PRODUCT DESCRIPTION

17

product. The main components of the GameEye prototype are the frontend, primary backend, machine learning backend, MongoDB database, and Elastic Database. These components are hosted on a single server, as opposed to each component having their own dedicated server in the real-world product. The web scraping is done in the prototype's primary backend.

4.2 Features and Capabilities

The GameEye prototype will provide support for user accounts. The prototype will provide robust user authentication using external authentication support and account management features to allow users to modify profile information and change their passwords. Users will have access to a personal watch-list, which they can curate by searching for games within the application that will feature auto-completion. Users will also have access to a list of the current most-watched games on the platform by all users. There are settings available for users to customize notifications they receive and desired frequency, the toggling of the archived resource visibility, and the toggling of impact score visibility.

The GameEye Prototype will utilize web scrapers to scrape data from multiple online sources; this data includes news articles and their content, which are then classified and scored using machine learning algorithms. Links to these articles and any thumbnails associated with them are provided to the user for viewing, which will then redirect users from the application to the source URL outside when interacted with. The web scrapers will be called twice a day to retrieve new articles for the database. The prototype will have cross-platform support between desktop and mobile platforms, and provide push notifications viewable to the user.

The GameEye prototype will utilize several techniques behind-the-scenes to mitigate potential risks related to database failures, web scraping failure, and security breaches. To protect against any kind of structural changes to source websites that could affect the web scrapers, RSS feeds will be scraped to ensure web scraping does not fail. To prepare for a situation where the IGDB is down, content from the IGDB will be stored on the GameEye main database for redundancy. In an instance where the GameEye main database fails, content will be cached on user devices so the application does not appear blank in case of a failure.

Security measures will be in place to ensure user information is safeguarded and the application is protected against different forms of cyberattack. To protect user account information, thorough database encryption will be used for login information alongside the use of a third party authentication provider. The GameEye platform will be made scalable with the use of load balancers and multiple instances to ensure protection of the main database and server in case of a heavy load or outright distributed denial of service (DDoS) attack. Both the back and front end will also ensure the use of proper coding practices to prevent cyber-attacks on the application such as NoSQL Injection, data exposure, and broken authentication or access controls.

4.3 Development Challenges

The largest expected obstacle while developing the prototype is learning the necessary technology, languages, and frameworks required for implementation. In both the front and backend, this prototype is in unfamiliar territory and requires time to become fully acclimated with the involved systems. Part of this process includes properly securing the necessary connections between multiple backend repositories to minimize issues. For the machine learning algorithm, a large magnitude of data needs to be manually collected and labeled to ensure the scraped data is labeled and scored accurately. In order to improve application connectivity and performance, the GameEye frontend is challenged with having to find the best way to vigorously cache content on the frontend. The backend is challenged with implementing the web scrapers in way to prevent source links and their content from breaking or becoming unviable in the case there are structural or design changes made to the platform where the sources originate.

5 Glossary

AAA: Classification of video games produced by a mid-sized or major game publisher that typically have large development and marketing budgets; analogous to "blockbuster" in film.

Angular Framework: Platform for building mobile and desktop applications.

API: Application Programming Interface; a set of functions and procedures allowing the creation of applications that access the features or data of an operating system, application, or other services.

AWS: Amazon Web Services; Amazon® subsidiary that provides on-demand cloud computing platforms and APIs

CSS: Cascading Style Sheets; used to stylize webpages.

Guest: Initial role for users who have not created an account on GameEye.

Hit List: List of highly watched video games by users.

HTML: Hypertext Markup Language; used as markup for documents meant to be displayed in a web browser.

IGDB: Internet Games Database; Database of known video games, accessed by REST API to populate GameEye's database

Indie Games: Games developed by individuals or smaller teams of people without the financial support of larger game publishers.

IntelliJ Idea: IDE developed by JetBrains to write Java applications and will be used in the back-end development of GameEye.

JavaScript: Object-oriented language used to create dynamic, interactive effects on webpages.

Jest JavaScript Framework: Testing framework maintained by Facebook Inc.

JSoup Library: Java library for working with real-world HTML.

JUnit Java Framework: A testing framework for Java.

Keras (**Python Deep Learning Library**): Open-source neural-network library written in Python.

MongoDB: A cross-platform document-oriented database program

Noise Filtering: Information/news articles shown that caters to an individual's content preferences.

OIDC Authentication: OpenID Connect; Authentication protocol based on the OAuth2.0 family of specifications.

PWA: Progressive Web Application; a type of application software delivered through the web which is built using common web technologies including HTML, CSS, and JavaScript.

Python: Interpreted, high-level, general-purpose programming language.

REST: Software architectural style used in creating web services.

RSS Feed: Web feed that allows users and applications to access updates to websites in a standardized, computer-readable format.

Scikit-learn Library: Software machine learning library for the Python programming language.

SpaCy Library: Open-source software library for advanced natural language processing. **Spring Framework:** Application framework and inversion of control container for the Java platform.

TensorFlow: Open-source software library for differential programming and dataflow; used in machine learning applications.

Tester: GameEye beta testers; users of the application in its prototype phase who will provide feedback on their experience.

Web Scraping: Data scraping for extracting data from websites.

WebStorm: IDE developed by JetBrains to write JavaScript code.
